Measurement Uncertainty

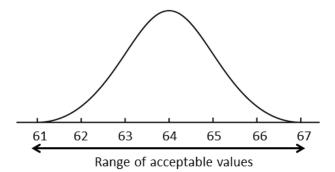

Chemical Pathology

Notes

What is Measurement Uncertainty?

With every result produced by a laboratory there is an associated uncertainty, which may be attributed to a number of small variations arising at any stage of the analytical process, from sample collection to analysis. It is important to understand that uncertainty is not the same as an error. An error implies that there is a difference between a measured value and the true value caused by an unknown factor, whereas uncertainty is an acceptable interval within which a result can fall. We are able to predict this interval by calculating the measurement uncertainty (MU) for each analyte in our repertoire.

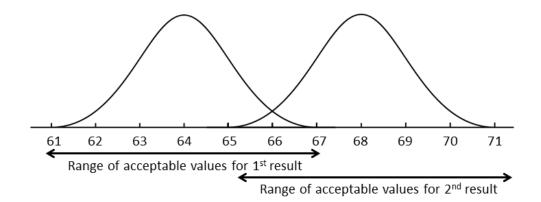

For example, if a creatinine result of 64 μ mol/L is reported by the laboratory, the result could actually lie somewhere between 61 and 67 μ mol/L once MU is considered (figure 1).

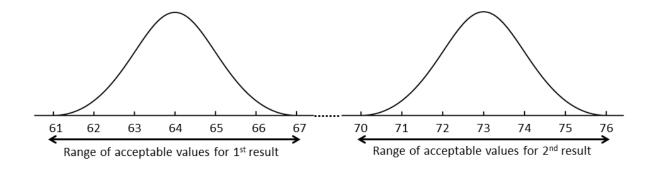

Why are we reporting uncertainty?

By estimating and reporting uncertainty, the laboratory can indicate the quality and reliability of the result produced. This information can then be used by clinicians and service users to compare a result to a cut-off limit or to a previous result from a sample on that same patient. Such information can be used by a clinician to determine whether the difference between two results is negligible due to uncertainty or significant due to a change in the condition of the patient. Without an estimate of MU, results cannot be compared either to previous results or reference values.

When there is a small change in the results, for example a change in creatinine from 64 to 68 μ mol/L, the range of acceptable values surrounding the two results may overlap (figure 2). The closer these results lie together the less likely they are to be significant but by knowing the MU we can be more confident in our ability to interpret the results.

Where there is no overlap, for example a change in creatinine from 64 to 73 μ mol/L, we can be certain that a true change has occurred (figure 3). The patient can then either be monitored or treated depending on any clinical cut-off limits that surround this result.

Expanded MU for each Analyte Currently Assayed across GRH and CGH Laboratories

The table below shows the expanded MU for each analyte currently assayed across the two laboratory sites. The expanded MU is the actual MU expressed with 95% confidence limit.

Analyte	Expanded MU (%)
Blood	
Alanine Aminotransferase (ALT)	5.49
Albumin	1.76
Alcohol	5.88
Alpha Foetoprotein (AFP)	5.68
